Dynare: Macroeconomic Modeling for All

Sébastien Villemot

MathWorks Finance Conference
October 12, 2023

Dynare in a nutshell

- MATLAB-based software for solving, simulating, and estimating macroeconomic models
- leading position in both policy institutions and academia
- originally for Dynamic Stochastic General Equilibrium models (DSGE), but also works for other theoretical paradigms
- user-friendly
- free/libre and open-source software
- community-driven

What Dynare brings to the community

- Easy description of macroeconomic models and operations on it, through a domain-specific language (DSL)
- Better focus on economic modeling task, without the need of specialized knowledge in applied mathematics and computer programming
- Less risk of coding mistakes, thanks to its proven and widely-tested implementation
- Research reproducibility, due to its open-source nature
- Means of communication of models among researchers and practitioners

Macroeconomic models

- Variables
 - ▶ endogenous: GDP, consumption, prices, unemployment, capital stock. . .
 - ▶ exogenous: determined outside of the model; have probability distribution
- Equations that determine endogenous variables
 - ▶ behaviour of agents (consumers, firms, government)
 - ▶ production technology
 - ▶ accounting and market-clearing
- Parameters
- Dynamics: contemporaneous variables can be influenced by
 - ▶ contemporaneous exogenous shocks
 - ▶ past variables
 - ▶ . . . and future variables (psychological expectations)
- Steady state: point of the state space where agents choose to remain in the absence of shock (exogenous variables are at their mean)

The problem of expectations

- How to model expectations?
- Rational expectations
 - ▶ agents are intelligent (they even have unlimited computational power)
 - ▶ agents know the model (equations, parameters, probability distributions of exogenous)
 - ▶ agents know the value of all past variables and contemporaneous shocks
 - ▶ all of this is common knowledge among agents
- Technically, assuming rational expectations means solving a fixed-point nonlinear functional equation over the state space
- Rational expectations are the benchmark for economists, but there are alternatives:
 - ▶ bounded rationality (learning process, rule-based decision-making. . .)
 - ▶ partial information

Solving a model under rational expectations

- Challenging fixed-point nonlinear functional equation problem
- Perturbation approach
 - ▶ compute Taylor expansion of the solution around the steady state
 - ▶ fast and robust, but accuracy suffers for large shocks and strong nonlinearities
 - ▶ extension: piecewise-linear solution (OccBin)
- Perfect foresight solution
 - ▶ approximation in the dimension of expectations: agents know the future value of shocks
 - ▶ provides exact nonlinear solution, at moderate computational cost
- Hybrid techniques: perfect foresight with expectation errors, (stochastic) extended path
 - ▶ build on several runs of perfect foresight algorithm
 - ▶ closer to rational expectations, incorporate some uncertainty
 - ▶ same good numerical properties as perfect foresight, but computationally more costly
- Global methods
 - ▶ functional approximation over a bounded domain
 - ▶ costly and fragile, not (yet) in Dynare

Classes of models

- Structural models (mostly Dynamic Stochastic General Equilibrium models, DSGE)
 - ▶ Real business cycle models (RBC)
 - ▶ New Keynesian models (NK)
 - ▶ Overlapping generations models (OLG)
 - ▶ Heterogenous agents new Keynesian models (HANK): limited support (simplified heterogeneity, or external toolkit by Thomas Winberry)
- Semi-structural models
 - ▶ Behavioural equations, but not necessarily derived from optimization
 - ▶ e.g. FRB/US or ECB/BASE
- Statistical models
 - ▶ Timeseries support (interface to X13-ARIMA-SEATS)
 - ▶ Estimation of VAR models possible, but inefficient
 - ▶ Better coverage in some alternatives like the BEAR toolbox

The Dynare language

Example: the neoclassical growth model

```
var c k;
varexo x;

parameters alph gam delt bet aa;
alph=0.5; gam=0.5; delt=0.02; bet=0.05; aa=0.5;

model;
  c + k = aa*(1+x)*k(-1)^alph + (1-delt)*k(-1);
  c^(-gam) = (1+bet)^(-1)*(aa*alph*(1+x(+1))*k^(alph-1) + 1 - delt)*c(+1)^(-gam);
end;

initval;
  k = 10; c = 1;
end;

steady;
check;

shocks;
  var x = 0.1;
end;

stoch_simul(order=2);
```

Computational tasks available

- Steady state computation
- Model solution and dynamic simulation
- Estimation
 - ▶ full information, Bayesian
 - ▶ full information, frequentist
 - ▶ limited information, method of moments (generalized or simulated)
- Forecasting
- Shock decomposition
- Sensitivity and identification analysis
- Optimal policy
 - ▶ under commitment (Ramsey problem)
 - ▶ under discretion
 - ▶ optimal simple rules

Mathematical and computational techniques employed

- Multivariate nonlinear solving and optimization
- Matrix factorizations
- Local functional approximation
- Filtering and smoothing
- MCMC techniques for Bayesian estimation
- Graph algorithms
- Optimal control
- Symbolic algebra
- Just-in-time bytecode compilation
- Divide-and-conquer methods (homotopy, block decomposition)

Architecture of Dynare

- Preprocessor
 - ▶ Standalone executable, written in C++ ($\sim 22\%$ of source code)
 - ▶ Parses the Dynare language
 - ▶ Symbolic algebra manipulations (e.g. derivatives, block decomposition)
 - ▶ Outputs M files (or MEX files) embedding the model and the requested operations
- M files
 - ▶ Represent $\sim 61\%$ of source code
 - ▶ For most high-level computational tasks
- MEX files
 - ▶ In modern Fortran or C++ ($\sim 16\%$ of source code)
 - ▶ For accelerating costly inner tasks
 - ▶ Specialized mathematical problems
 - ▶ Stacked model Jacobian construction
 - ▶ Parallelized law-of-motion of particles in particle filtering
 - ▶ Machine or bytecode representation of model equations and derivatives
- Testsuite: unit and integration tests

Leveraging the MATLAB platform

- First version of Dynare (1994) was in Gauss; switch to MATLAB occurred around 2000, because of its popularity in academia
- Intuitive and convenient syntax for scientific computing
- Easier to learn by economists than general programming languages
- Platform available in most policy institutions
- Good performance, improving over time
- Several environments
 - ▶ on the desktop
 - ▶ on servers (MATLAB Production Server)
 - ▶ in the web browser (MATLAB Online)

An open-source development model

- License: GNU General Public License (version 3)
- Development on our public GitLab instance
- Bug reports through GitLab issues or the forum
- Merge requests possible from anyone
- Continuous Integration (CI) for quality assurance
- Cooperation with other open-source projects (GNU Octave, OpenBLAS, SuiteSparse, Debian, Homebrew. . .)
- Recently accepted as a NumFOCUS project

The community

- Core developers
- Advisory committee
- Institutional sponsors and users
 - ▶ central banks
 - ▶ ministries of economy and finance
 - ▶ international organizations
- Academic users
 - ▶ professors and researchers
 - ▶ PhD and master students
- Online forum for help and discussions
- Annual events
 - ▶ Academic conference
 - ▶ Summer school (for beginners)
 - ▶ Advanced users workshop

Future projects

- Performance improvements on (very) large models
- Heterogenous agents new Keynesian (HANK) models
- Global solution methods
- Sequential Monte-Carlo (SMC) sampler
- Better solver for mixed-complementarity problems (MCP)
- More interactive model building (à la TROLL)
- Graphical user interfaces
